## FORENSIC STUDIES

Inc.

Occasionally, structures do not interact with the soils as intended during design. This is evidenced by various types of movements or distress, including:

- Heave of Floors or Foundations
- Cracking of Foundation Walls
- Cracking of Drywall and Framing Distress
- Water Entry into Structures
- Settlement of Supporting Soils
- Excessive Movement of Retaining Walls
- Degradation of Pavements
- Environmental Site Assessments, Industrial Hygiene, Mold and Moisture Evaluations

A. G. Wassenaar, Inc. works with the Client in order to develop a program to provide prudent and cost effective stabilization of the structure. This generally begins with a site visit and review of pertinent construction documents. If further investigation is warranted, a program is developed with the Client's input and is designed to provide the specific information needed to understand the situation and to provide remedial recommendations for the structure.
